2008 landmark judgement by German Bundesverfassungsgericht (BVerfG):

Basic right to confidentiality and integrity of IT systems

“1. Das allgemeine Persönlichkeitsrecht (Art. 2 Abs. 1 i.V.m. Art. 1 Abs. 1 GG) umfasst das Grundrecht auf Gewährleistung der Vertraulichkeit und Integrität informationstechnischer Systeme.“

Stealthy infiltration of IT systems is problematic:

„2. Die heimliche Infiltration eines informationstechnischen Systems, mittels derer die Nutzung des Systems überwacht und seine Speichermedien ausgelesen werden können, ist verfassungsrechtlich nur zulässig, wenn tatsächliche Anhaltspunkte einer konkreten Gefahr für ein überragend wichtiges Rechtsgut bestehen. ## Definitions

- Is a set of instructions that cause a site's security policy to be violated.

*[M. Bishop, Introduction to Computer Security]*

- A program implemented in hardware, firmware, or software, and whose purpose is to perform some unauthorized or harmful action.

*[ISO/IEC 2382-8]*

- Hardware, software, or firmware capable of performing an unauthorized function on an information system.

*[National Information Systems Security (INFOSEC) Glossary 2000]*

Malicious logic is also known as malicious code or **malware** (Malicious software).

- Trojan Horses
  - Programs with a covert purpose
- Viruses
  - Programs that replicate
- Worms
  - Propagate autonomously from system to system
- Logic Bombs
  - Hidden code, triggered by external event

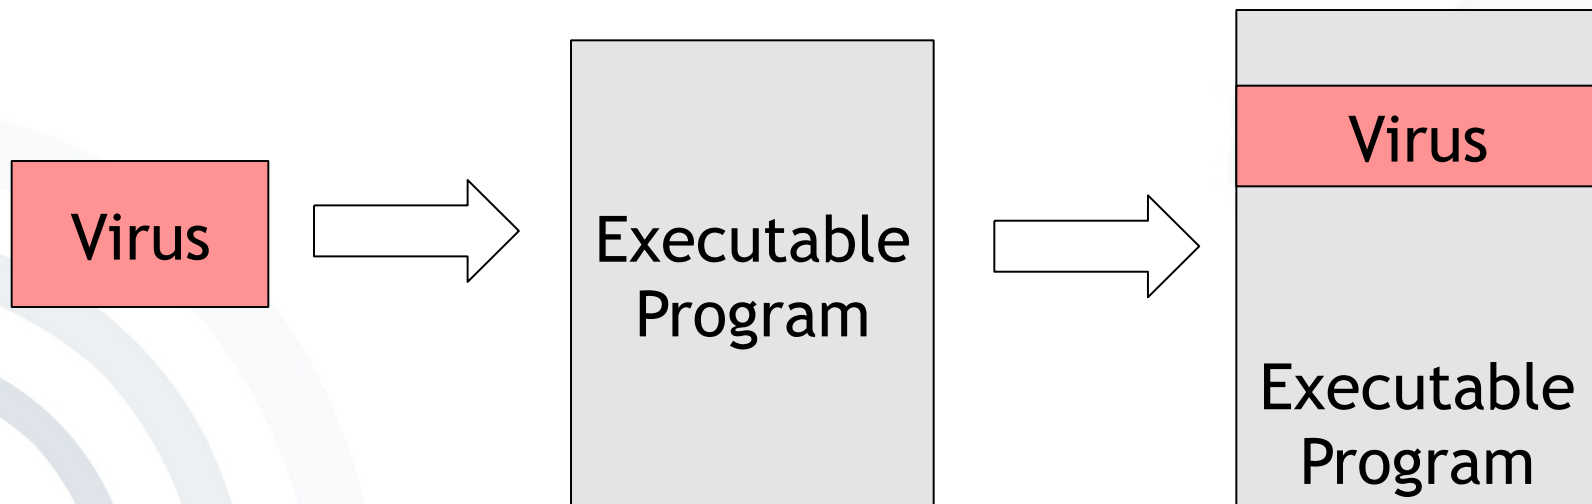

- Program with an *overt* purpose (known to user) and a *covert* purpose (unknown to user)
  - Often called a Trojan
  - Named by Dan Edwards in Anderson Report [Anderson72]
- Example: NetBus
  - Designed for Windows NT system
  - Victim uploads and installs it:
    - Usually disguised as a game program, or integrated within one
  - Acts as a server, accepting and executing commands for remote administrator
    - This includes intercepting keystrokes and mouse motions and sending them to attacker.
    - Also allows attacker to upload, download files

Program that replicates itself, e.g. by inserting itself into one or more files, and that may perform some other action, too:

- *Insertion phase*: Virus is inserting itself into a file.
- *Execution phase*: Virus is performing some (possibly null) action.

- Boot Sector Infector
  - Inserts itself into the boot sector of a disk
- Executable Infector
  - Infects executable programs, e.g. .EXE or .COM programs
  - May prepend itself (as shown) or put itself anywhere, fixing up binary so it is executed at some point
- Multipartite Virus
  - Can infect multiple platforms (e.g. either boot sectors or executables)
- TSR Virus (Terminate and Stay Resident)
  - Stays active in memory after the application is completed
- Stealth Virus
  - Conceals its presence on a system

- **Encrypted Virus**
  - Is enciphered except for a small deciphering routine
- **Polymorphic Virus**
  - Changes its form each time it inserts itself into another program
- **Macro Virus**
  - Composed of a sequence of instructions that are interpreted rather than executed directly
  - Can infect either executables (Duff's shell virus) or data files (Highland's Lotus 1-2-3 spreadsheet virus)
  - Independent of machine architecture
- **Retro Virus**
  - Attacks anti-virus software present on the system

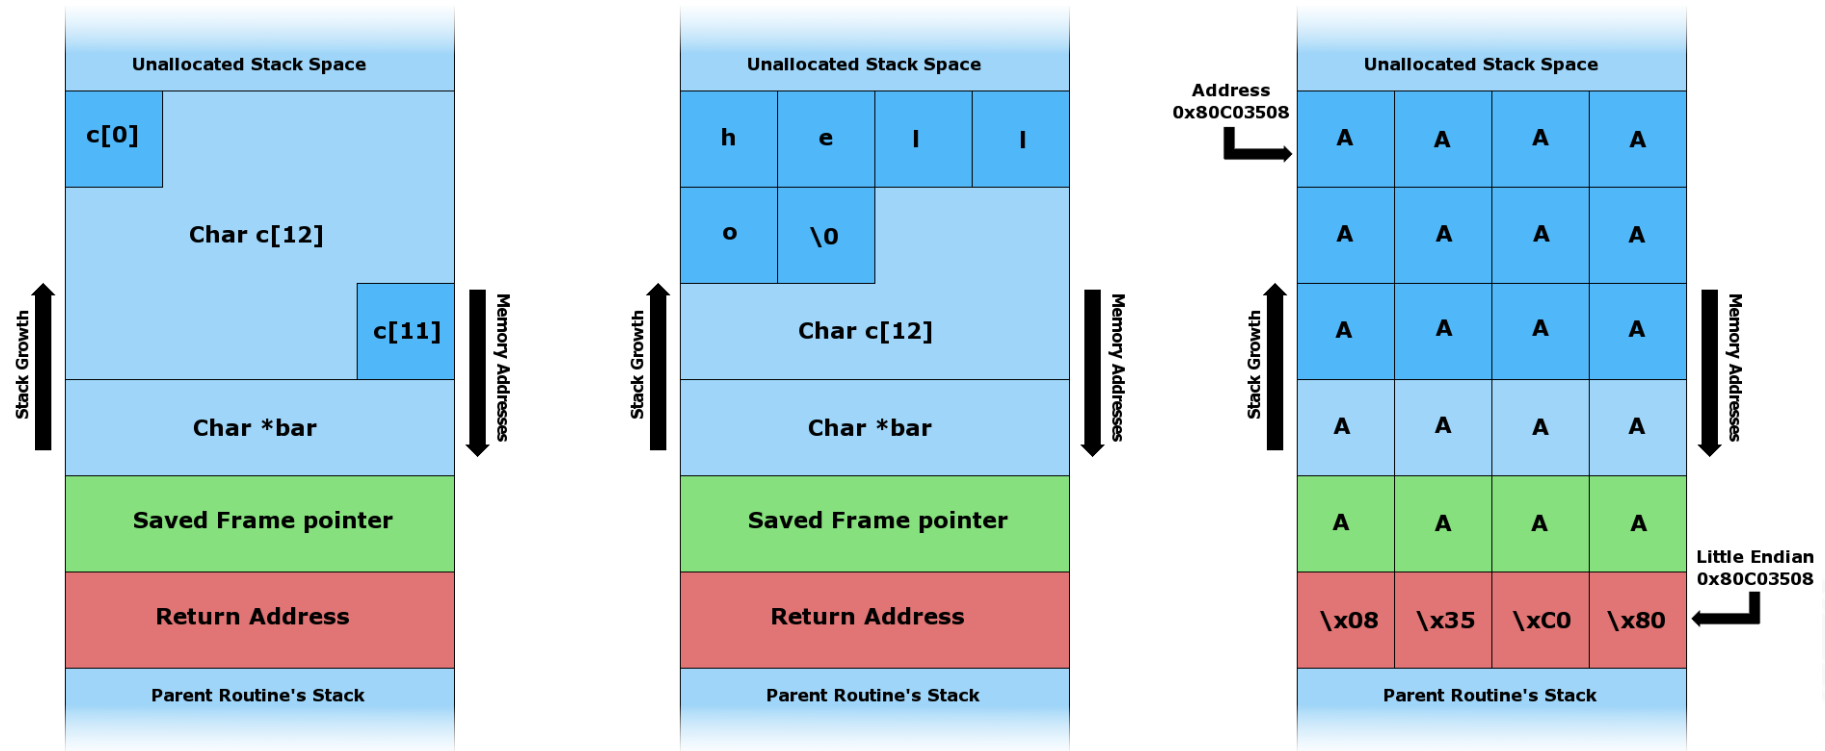

- A program that copies itself from one computer to another
- Origins: distributed computations
  - Animations, broadcast messages
- Segment
  - part of program copied onto workstation
  - processes data, communicates with worm's controller
  - Any activity on workstation causes segment to shut down.

- A program that performs an action that violates the site security policy when some external event occurs
- Example: program that deletes company's payroll records when one particular record is deleted
  - The “particular record” is usually that of the person writing the logic bomb.
  - If/when the person is fired and the payroll record deleted, the company loses *all* those records.

- Introduction
- Security Threats
  - Malicious Logic
  - Buffer Overflow
  - Mobile Code
- Operating System Security
- Improving Security

- Buffer overflow software bug
  - data larger than the variable allocated for it
  - can overwrite a procedure return address in the procedure call stack in memory
- Persisted for decades
  - Users do not bother to install patches supplied (free) by software vendors.
- Example of vulnerability that permits remote injection of hostile code, recruiting bot nets for later DDoS attacks

# Buffer Overflow (2)

Before data is copied.

"hello" is copied.

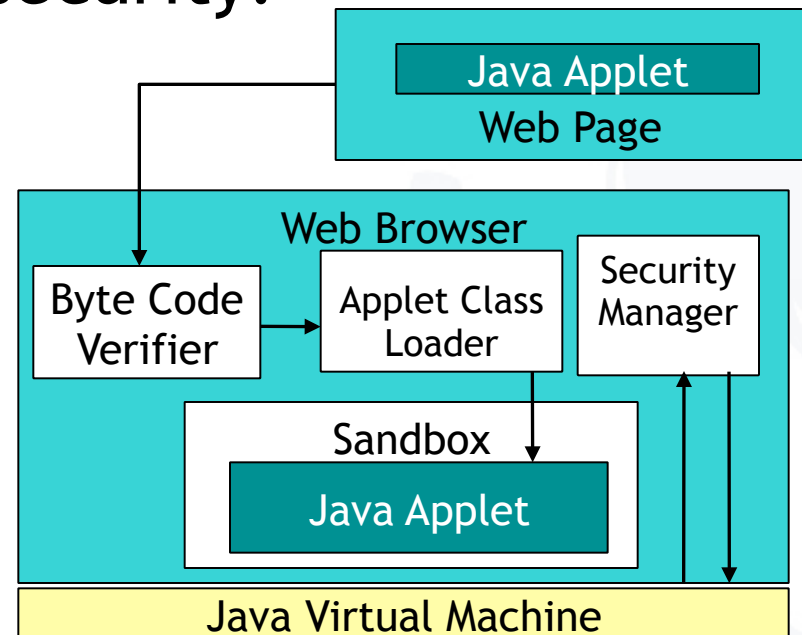

"AAAAAAAAAAAAAAAAAAAAAA  
AA\x08\x35\xC0\x80" is  
copied.

- Introduction
- Security Threats
  - Malicious Logic
  - Buffer Overflow
  - Mobile Code
- Operating System Security
- Improving Security

- Download code and run it locally
- Two common mobile code systems:
  - Java Virtual Machine
  - Microsoft ActiveX, .NET
- Java Virtual Machine security:

- Environment maintains a security manager that cannot be replaced.
- Security managers can be set to prevent access to local resources.
- Downloaded classes are stored separately from local classes.
- Byte code is checked for validity.

- Introduction
- Security Threats
- Operating System Security
  - Unix
  - Windows
  - Mobile OSs
- Improving Security

# OS Security Considerations

- The whole code which is executed in the kernel is very security critical (supervisor mode!) .
- It is the target of a lot of attacks to gain root privileges by manipulating kernel functions.

OS Kernel

- Identification
  - Recognition of human individuals
- Authentication
  - Secure confirmation of users' identifiers
- Access Control
  - Restricting usage of a service to authorized users
- Audit
  - Monitoring of system activities

- Introduction
- Security Threats
- Operating System Security
  - Unix
  - Windows
  - Mobile OSs
- Improving Security

- In the Unix operating system there are two parts:
  - Kernel
  - User space
- Any programming code in the kernel space has full access to the computer it is running on.
- Code running in the user space has access rights based on the User ID (UID) it is running under:
  - UID 0 is reserved for the super user or root and the kernel automatically gives this UID complete access.
- Note the difference between kernel and root access:
  - Kernel processes can access anything.
  - Root processes can order the kernel to access anything.

- IDs
  - User Identification number (UID)
  - Root/super user (UID 0)
  - Group Identification number (GID)
- Authentication
  - Password: /etc/passwd
    - User name (login name)
    - Password, encrypted
      - usually modified DES (or MD5, SHA...)
      - One way function, it is impossible to decrypt the password.
      - At login the entered password is encrypted and compared to file.
  - User id (number)
  - Login group id (number)
  - GCOS (Comment, usually real-life name)
  - Home directory
  - Program to be executed at login, usually shell

## ■ Access Control

- A file has owner and group id (sometimes several).
- A process has owner and group id (sometimes several).
- Kernel verifies permissions before executing system calls:
  - If owner uid=0 (root), everything is allowed
  - Otherwise the uid and gid of the process and object are compared in this order and permission for the operation is searched for based on owner, group and other (world) rights

## ■ Auditing

- Permanent Logging
- Automatically recorded events
- Manually set logging

- Introduction
- Security Threats
- Operating System Security
  - Unix
  - Windows
  - Mobile OSs
- Improving Security

- Provides security controls access and auditing
- Implements the standard subject/object security model
  - Subject - process or thread running on behalf of the system or an authenticated user
  - Object - individually secured entity such as a file, pipe, or even a process. Access control may vary between different objects.
  - Kernel mode, User mode
- Controls applied to core OS elements like processes and sockets in addition to the more traditional file system elements (NTFS).
- Problems
  - Unexpected use of extensible elements like word macros or extensible DLL's
  - Unprotected file systems
  - Attempts at backwards compatibility with older version of Windows caused some security problems (NetBIOS and FAT).

- Identification
  - User Account
  - Security ID (SID) - A globally unique ID that refers to the subject (user or group)
- Authentication
  - Password, stored as hash value
  - Secure attention sequence CTRL+ALT+DEL
  - Security Accounts Manager
- Access Control
  - Object - Individually secured entity such as a file, pipe, or even a process
  - Rights - actions associated between object and subject (Read, write, execute, audit)
  - Access token - the runtime credentials of the subject
  - User Access Control (UAC) - administrative privileges not available by default at all times, but only after confirmation via UAC dialog box.

- Access Control
  - Access control list (ACL)
    - Associated with an object
    - Ordered list
    - Each access control entry (ACE) contains a subject and a right.
    - Evaluated by the security subsystem to determine access to protected objects
    - Discretionary ACLs control access
    - System ACLs control audit
- Auditing
  - Security Reference Monitor
  - Local Security Authority
  - Event Logger
  - If auditing applies and what is to be audited is determined by the Audit Policy

Once upon a time...

- Closed platforms
- No additional software could be installed.
- Limited functionality

# Mobile Devices Today

- Open platforms
- Lots of software can be installed:
  - For different purposes
  - From different vendors
- Communication with different protocols possible:
  - GSM/GPRS, UMTS
  - Bluetooth, Infrared, WLAN
- Private and confidential data can and will be stored on the mobile device.
- Camera is (in many cases) included.

- Risks of Malware
  - Viruses, Worms, Dialler, Trojan Horses, etc.
- Passwords can (and will most likely) be deactivated.
- External storage media enables potential attackers to steal private information.
- Different communication protocols can be used to attack device or steal data.
- Camera also introduces new risks:
  - Stealing paper based confidential information
  - Invasion of personal privacy

- No effective distribution of rights and separation of processes
- No secure path between applications and kernel
- Can be synchronized with any PC
- Unsatisfactory password protection
- No certificate management
- Manipulated program could act with all user authorization.
- Additional security software exists, but there are still security risks.

# Pocket PC / Windows Mobile

- Offers no encryption of data
- No memory protection
- Supports ActiveX and Java
- Passwords deactivated by default
- Each application can adjust its priorities, terminate other applications or can access their memory.
- External storage media enables potential attackers to steal private information.
- No protection from malware
- Code signing mechanisms exist, but:
  - Only origin of software can be checked.
  - Administration of certificates is not possible
- Additional security software exists, but cannot resolve design failures.

- Provides better protection than Palm OS and PocketPC 2003
- Device can be administered by ACLs.
- Certain contents can only be synchronized with certain servers.
- Certificate management is installed, but the user cannot check the security status of the device.
- Hardly any additional security software is available.

- The unit of trust is the OS process:
  - Trusted Computing Base: the kernel, file server and, on open devices, the software installer and its registry
  - Trusted Computing Environment: other system components
  - Applications
- Capabilities are used to control access to sensitive resources:
  - Every process has a set of capabilities, and its capabilities never change during its lifetime.
  - The capabilities are stored in the kernel's memory.
  - Capabilities must be checked for each use of service.
- Data caging protects files against unauthorised access:
  - File access control

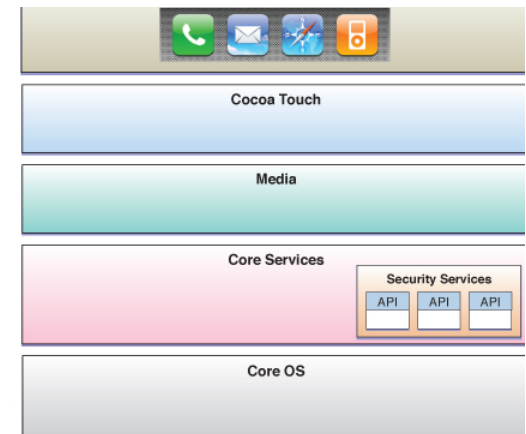

- Provides user with largest number of security functions
- Security gaps exist, while not being as prominent.
- 2005:
  - *“We think that 2005 is going to be a real breakout year for Linux on cellphones,” Trolltech CEO Haavard Nord told LinuxDevices.com. “There seems to be a huge interest in Linux. Linux is just now getting mature for the market. Currently, we’re working with more than 20 manufacturers [who are] building Linux phones today,” he said. [LinuxDevices.com]*
- 2010:
  - Nearly every manufacturer
  - E.g. Samsung i7500
  - For details see:
  - [www.linuxfordevices.com/c/a/Linux-For-Devices-Articles/Linux-Mobile-Phones/](http://www.linuxfordevices.com/c/a/Linux-For-Devices-Articles/Linux-Mobile-Phones/)

- BlackBerry became a big problem in some countries:
  - United Arab Emirates: BlackBerrys are a "national security risk".
  - India
  - Saudi Arabia
- (Reuters) - More than a million BlackBerry users may have key services in Saudi Arabia and the UAE cut off after authorities stepped up demands on smartphone maker Research In Motion for access to encrypted messages sent over the device.
- According to an internal note from the Indian communications ministry seen by the Economic Times in India, BlackBerry has the infrastructure for solutions that would allow agencies to track messages and monitor internet traffic, but had not provided "the architect of the solution as well as the communication path for the service" [<http://www.security-technologynews.com/news/indias-blackberry-security-concerns.html>].
- All of this does not address the security of the (proprietary) Blackberry Phone platform, e.g. its operating system.

- The iOS security APIs are located in the Core Services layer.
- The iOS security implementation includes a daemon called the Security Server that implements several security protocols:
  - keychain items
  - root certificate trust management
- CFNetwork
  - High-level API that can be used by applications to create and maintain secure data streams and to add authentication information to a message.
- iOS provides process sandboxing:
  - An application running in iOS can see only its own keychain items and files.
- Digital signatures are required on all applications for iOS.
- Apple adds its own signature before distributing an iOS application.
- Each application is granted access permissions for certain system services when it's signed by Apple, Inc.

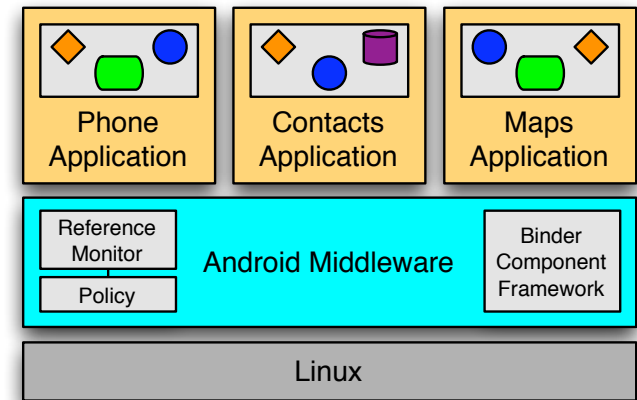

[<http://developer.apple.com>]

- **System security**
  - Secure boot chain
  - System Software authorization
- **Encryption and data protection**
  - Hardware security features
  - File data protection
- **App security**
  - App code signing
  - Runtime process security
- **Network security**
  - Industry standard networking protocols that provide secure authentication and encryption of data in transmission (SSL, TLS, VPN, Single Sign-on).
- **Internet services**
  - Apple's network-based infrastructure for messaging, syncing and backup
- **Device controls**
  - Methods that prevent unauthorized use of device and enable it to be remotely wiped if lost or stolen
  - Passcode protection

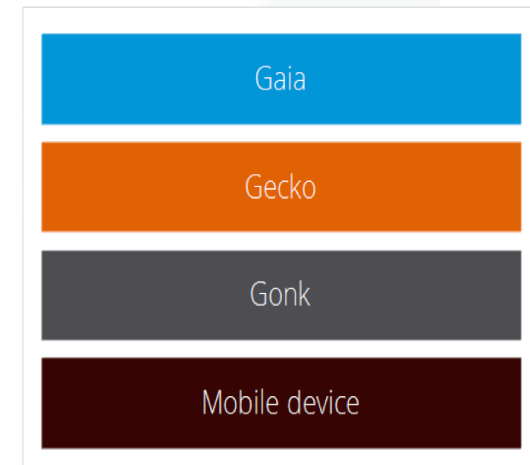

- A Linux platform programmed with Java and enhanced with its own security mechanisms tuned for a mobile environment
- Each application declares which permission it requires at install time.
- Android *permissions* are rights given to applications to allow them to do things like:
  - directly dialling calls (which may incur tolls),
  - disclosing the user's private data, or
  - destroying address books, email, etc.
- When installed, applications are given a unique UID, and the application will always run as that UID on that particular device. The UID of an application is used to protect its data and developers need to be explicit about sharing data with other applications.
- Each process is running in its own address space (Dalvik virtual machine).
- The developer signs application .apk files, and the package manager verifies them.

- Data encryption
  - Support of several cryptographic algorithms, including AES, RSA, SHA1, SHA256, HMACSHA1, HMACSHA256, Rfc2898DeriveBytes
- Secure sockets layer (SSL) certificates
  - The Windows phone internet explorer shows a warning or error if the certificate is not valid or not issued by a trusted authority
- App management by Windows Phone app platform
  - Protect end user experience, especially
    - Avoid, that apps affect phone experience
    - Ensure, that a apps are easy to uninstall and that they uninstall completely
    - No access to the user's information without informing the user
    - No billable events without getting permission from the user
  - Application vetting
    - Apps required to go through the Windows Phone Store to be tested and digitally signed.
  - Application isolation
    - Developers use the Silverlight platform where the sandbox concept is used to provide an environment where applications have limited privileges.

- Firefox OS is an integrated technology stack consisting of four levels:
  - **Gaia**: the suite of web apps that makes up the user experience
  - **Gecko**: the application runtime layer that provides the framework for app execution
  - **Gonk**: the underlying Linux kernel, system libraries, firmware and device drivers that everything runs on top of
  - **The mobile device**: the mobile phone running the Firefox OS
- Security architecture
  - Multi-layered security model to mitigate exploitations risks at every level
  - Gecko as gatekeeper to enforce security policies designed to protect the mobile device from misuse

Based on [www.developer.mozilla.org]

- Secure system deployment
  - Security measures are used throughout the technology stack.
  - File system privileges are enforced by Linux's access control lists (ACLs).
  - System apps are installed on a volume that is read-only (except during updates, when it is temporarily read-write).
- Secure system update
  - Update origin (verify the source location protocol:domain:port of the system update and manifest)
  - File integrity (SHA-256 hash check)
  - Code signature (certificate against a trusted root)
- App Security
  - Firefox OS limits and enforces the scope of resources that can be accessed or used by apps, while also supporting a wide range of apps with varying permission levels.

- **Virus scanners** try to identify viruses according to a certain characteristic (virus signature) stored in a database.
- **Code Signing** helps to distinguish authorized code from other code.
- **A Trusted Operating Base** can then prohibit the execution of not authorized code e.g. viruses on a system.
- **Checksums and/or Encryption** make it possible to detect/avoid modifications done by a virus.
- **Intrusion Detection Systems (IDS)** monitor a system to detect processes which may be the result of a virus infection.
- **Heuristic virus scanners** try to identify a virus with a forecast about the runtime behaviour of code (sophisticated approach, but not really efficient).

- Trust

“An entity can be trusted if it always behaves in the expected manner for the intended purpose.” *[Sandhu, Zhang 2005]*
- Entity
  - a platform, or an application or service running on a platform
  - A platform can be a personal computer, personal digital assistant (PDA), smart phone, etc.
- US Department of Defense Security Policy: „trusted system or component“ defined as „one which can break the security policy“
- Also called “Trustworthy Computing”, “Safer Computing”... *[Trusted Computing FAQ]*

# Trusted Computing Initiatives

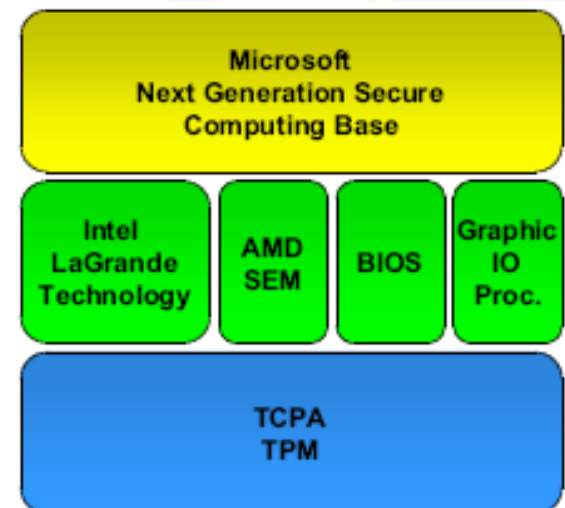

- 1999: TCPA (since 2003: TCG)
- 2003: NGSCB by Microsoft (formerly “Palladium”)
- Intel Trusted Execution Technology (formerly LaGrande)
- TrustZone by ARM (2005)
- Project Trusted Mobile Platform (2003-2004)
  - By Intel, IBM and DoCoMo

**TrustZone**<sup>®</sup>  
Security Foundation by ARM<sup>®</sup>

Applications  
Operating System

PC Chipsets

Secure  
Hardware

- Trusted Computing Platform Alliance was founded in 1999 by Compaq, HP, IBM, Intel and Microsoft
- 2003 - Trusted Computing Group (TCG)
- Currently more than 100 members
- Changes to platform
  - Extra: Trusted Platform Module (TPM)
  - Software changes: BIOS + OS
- Main properties
  - Secure bootstrap
  - Platform attestation
  - Protected storage

# Trusted Platform Module

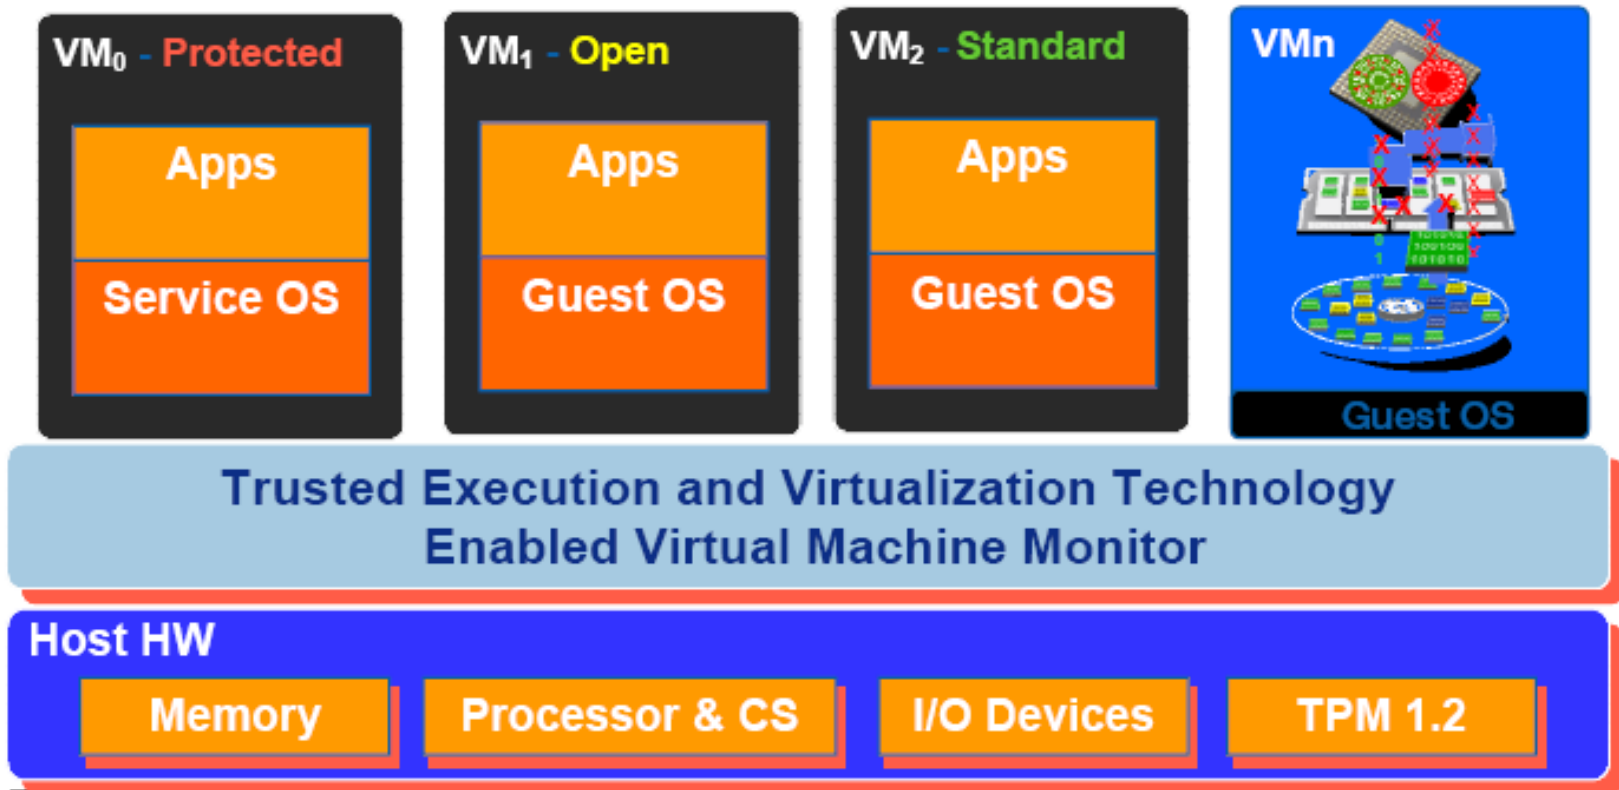

Module on the motherboard that:

- Protects secrets from attackers
- Performs cryptographic functions
  - RSA, SHA, RNG
  - Meets encryption export requirements
- Can create, store and manage cryptographic keys
- Provides a unique Endorsement Key (EK)
- Performs digital signature operations
- Holds Platform Measurements (hashes)
- Anchors chain of trust for keys, digital certificates and other credentials

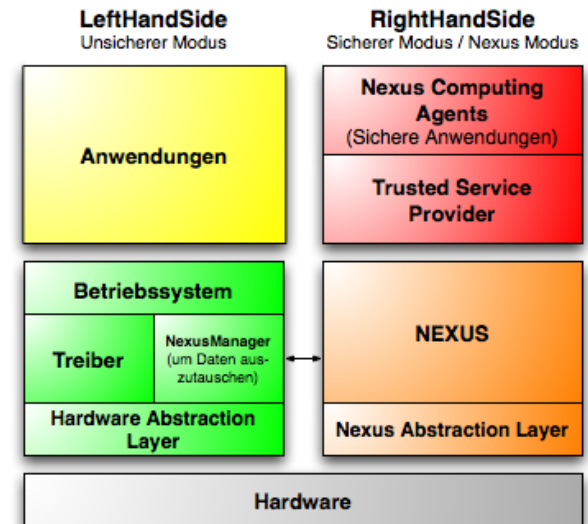

- Domain separation
- Protected execution
- Sealed storage
- Trusted channel to graphics and input devices
- Authentication of launch of a protected environment
- Attestation of platform ID

- Virtual Machine Monitor („Hypervisor“)

## Next Generation Secure Computing Base

- **Attestation**
  - Ability to verify the operating environment
    - Remote verification
- **Strong Process Isolation**
  - Memory isolation (curtained memory)
- **Sealed Storage**
  - Data bound to operating environment
    - Application, OS, drivers, CPU, hardware, TPM
- **Secure Path to I/O:**
  - No keyboard sniffing
  - No frame buffer reading/writing

## Trusted Platform Module Services

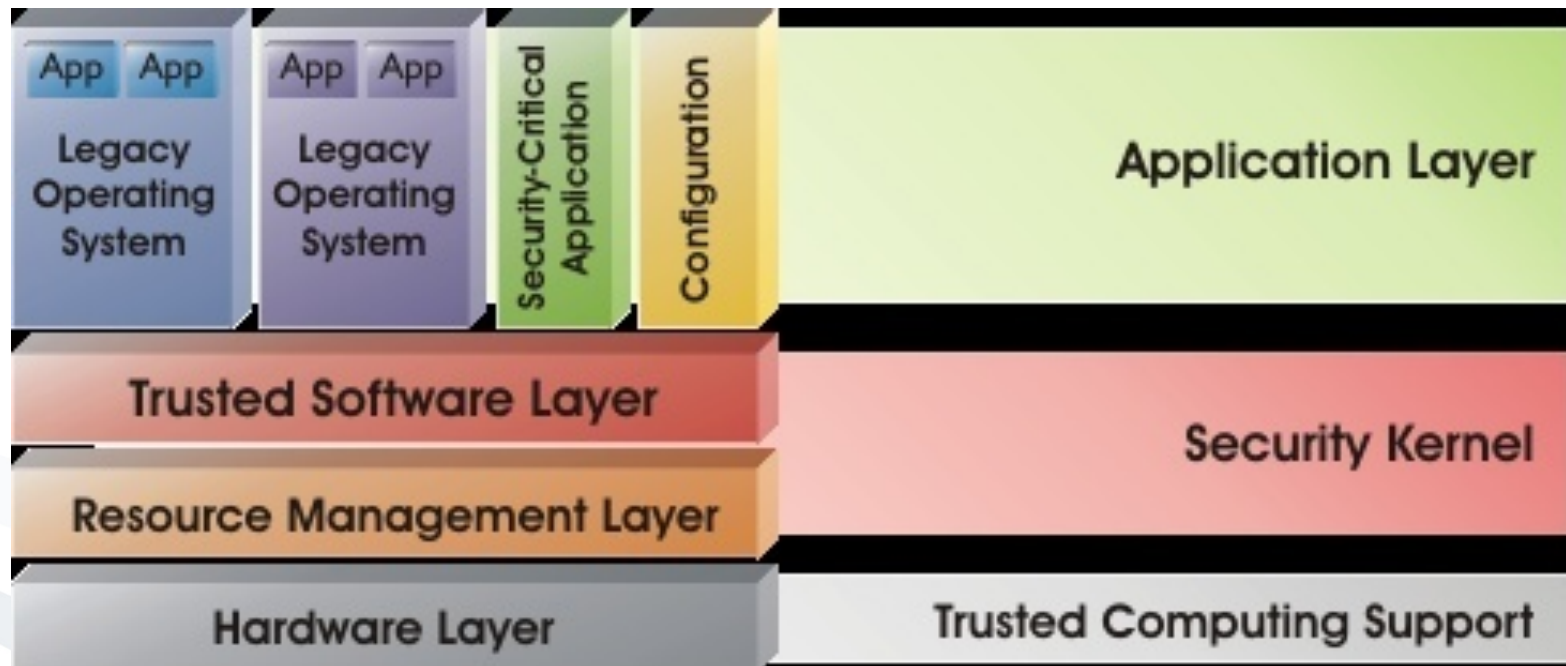

- BitLocker Drive Encryption (Secure Startup)
  - Ensures Boot Integrity
  - Resilient to Attack
  - Locks System when tampered with
  - Encrypts User Data and System Files
  - Provides Umbrella Protection for Third Party Applications
  - Simplifies the Recycling Process
  - Speeds Data Deletion

## European Multilaterally Secure Computing Base (EMSCB)

- A trustworthy computing platform
- Employing open standards
- Solving many security problems of conventional platforms.
- Hardware functionalities provided by Trusted Computing
- Security kernel based on a microkernel
- Efficient migration of existing operating systems

[EMSCB]

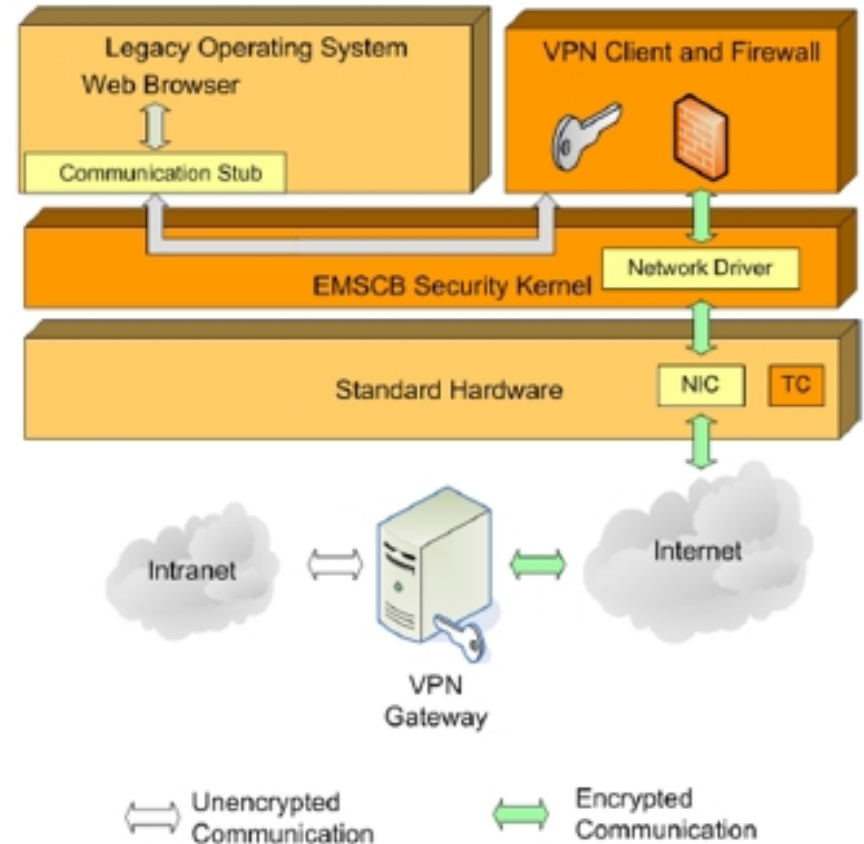

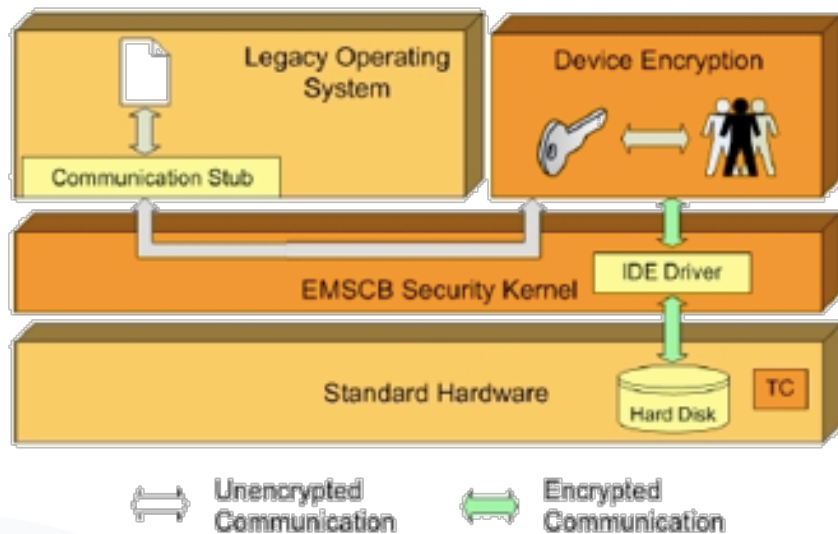

## ■ Architectural Layers

- Implementation of EMSCB architecture
- Security and access policies
- Based on PERSEUS security framework
- L4 micro kernel
- Two prototypes as proof of concept (June 2006):
  - Turaya.Crypt: Device/drive encryption, transparent for user.
  - Turaya.VPN: Secure IPSec VPN-Client compatible with conventional VPN servers.
