 - UMTS (3G)
 - Long Term Evolution (3.9G, 4G)
 - 5th Generation (5G): mobile broadband
- Roaming

There are two major paradigms for data transmission in communication networks:

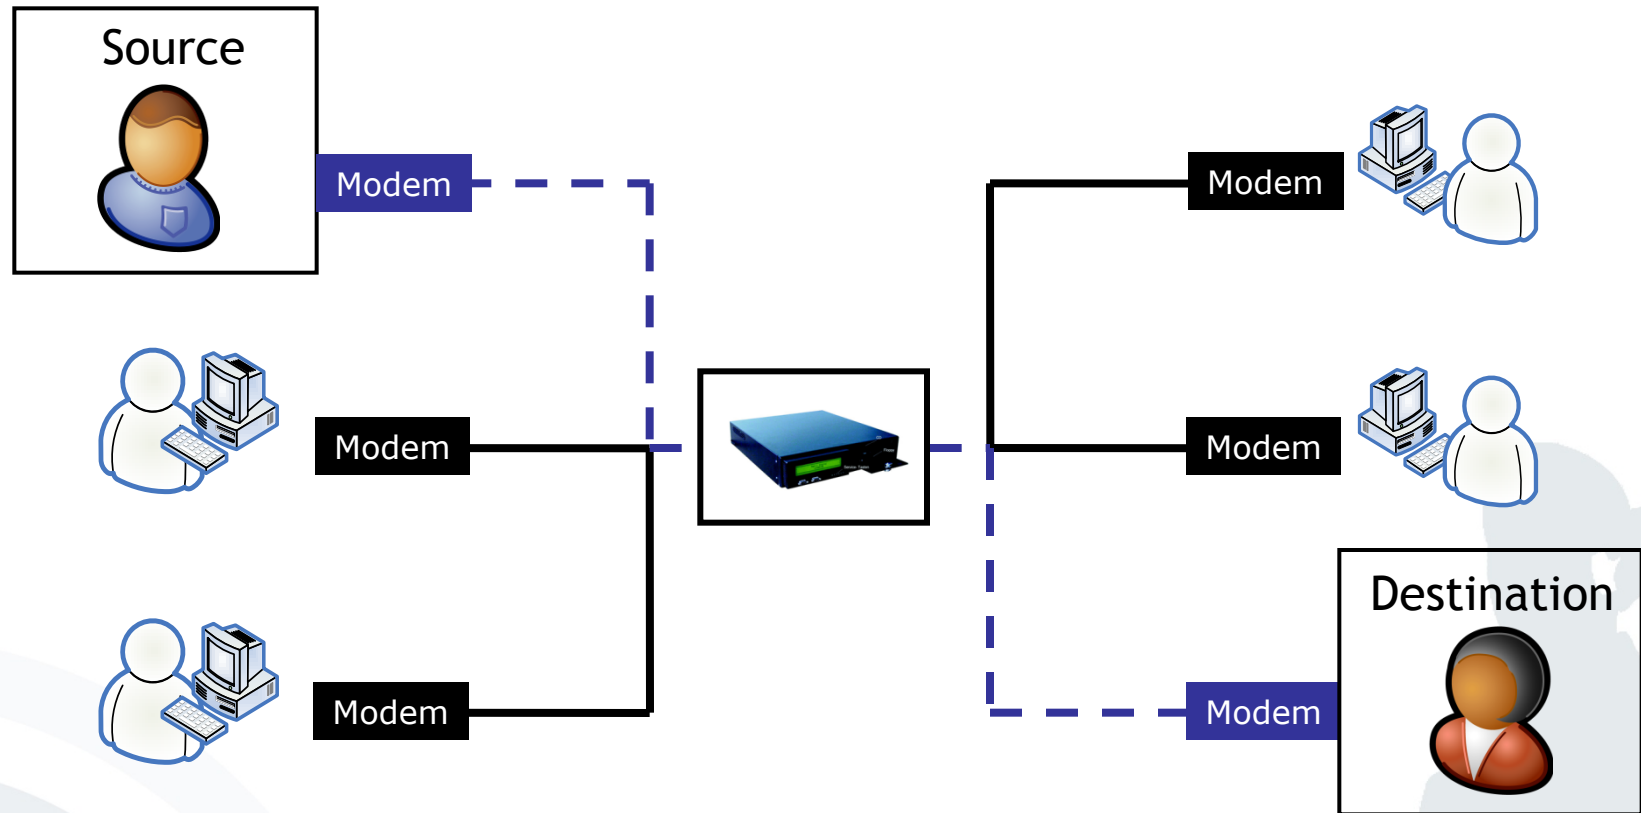

▪ **Circuit-Switched:** In circuit-switched networks, the communication line is used exclusively for the communicating parties.

- Connections are **exclusive** ➡ even if no data is transferred, the network resources are used.
- In reality, the typical usage for voice connections is 30% of the network's capacity - for data transmission it is less than 10%.
- The **duration of a connection** is used for billing purposes
- Example: *Circuit Switched Data (CSD)* and *High-Speed Circuit Switched Data (HSCSD)* for Mobile Data Services

▪ **Packet-Oriented:** In packet-oriented networks, the communication is divided into several packets, which get addressed and transferred using a **shared** transmission medium.

- The connection is kept all the time (always on). However, the network is only used when data is transmitted.
- The capacity of the communication network is allocated dynamically.
- For billing purposes, the **amount of transferred data** is used.
- Example: GPRS for Mobile Data Services

Mobile Data Services Circuit-Switched Networks

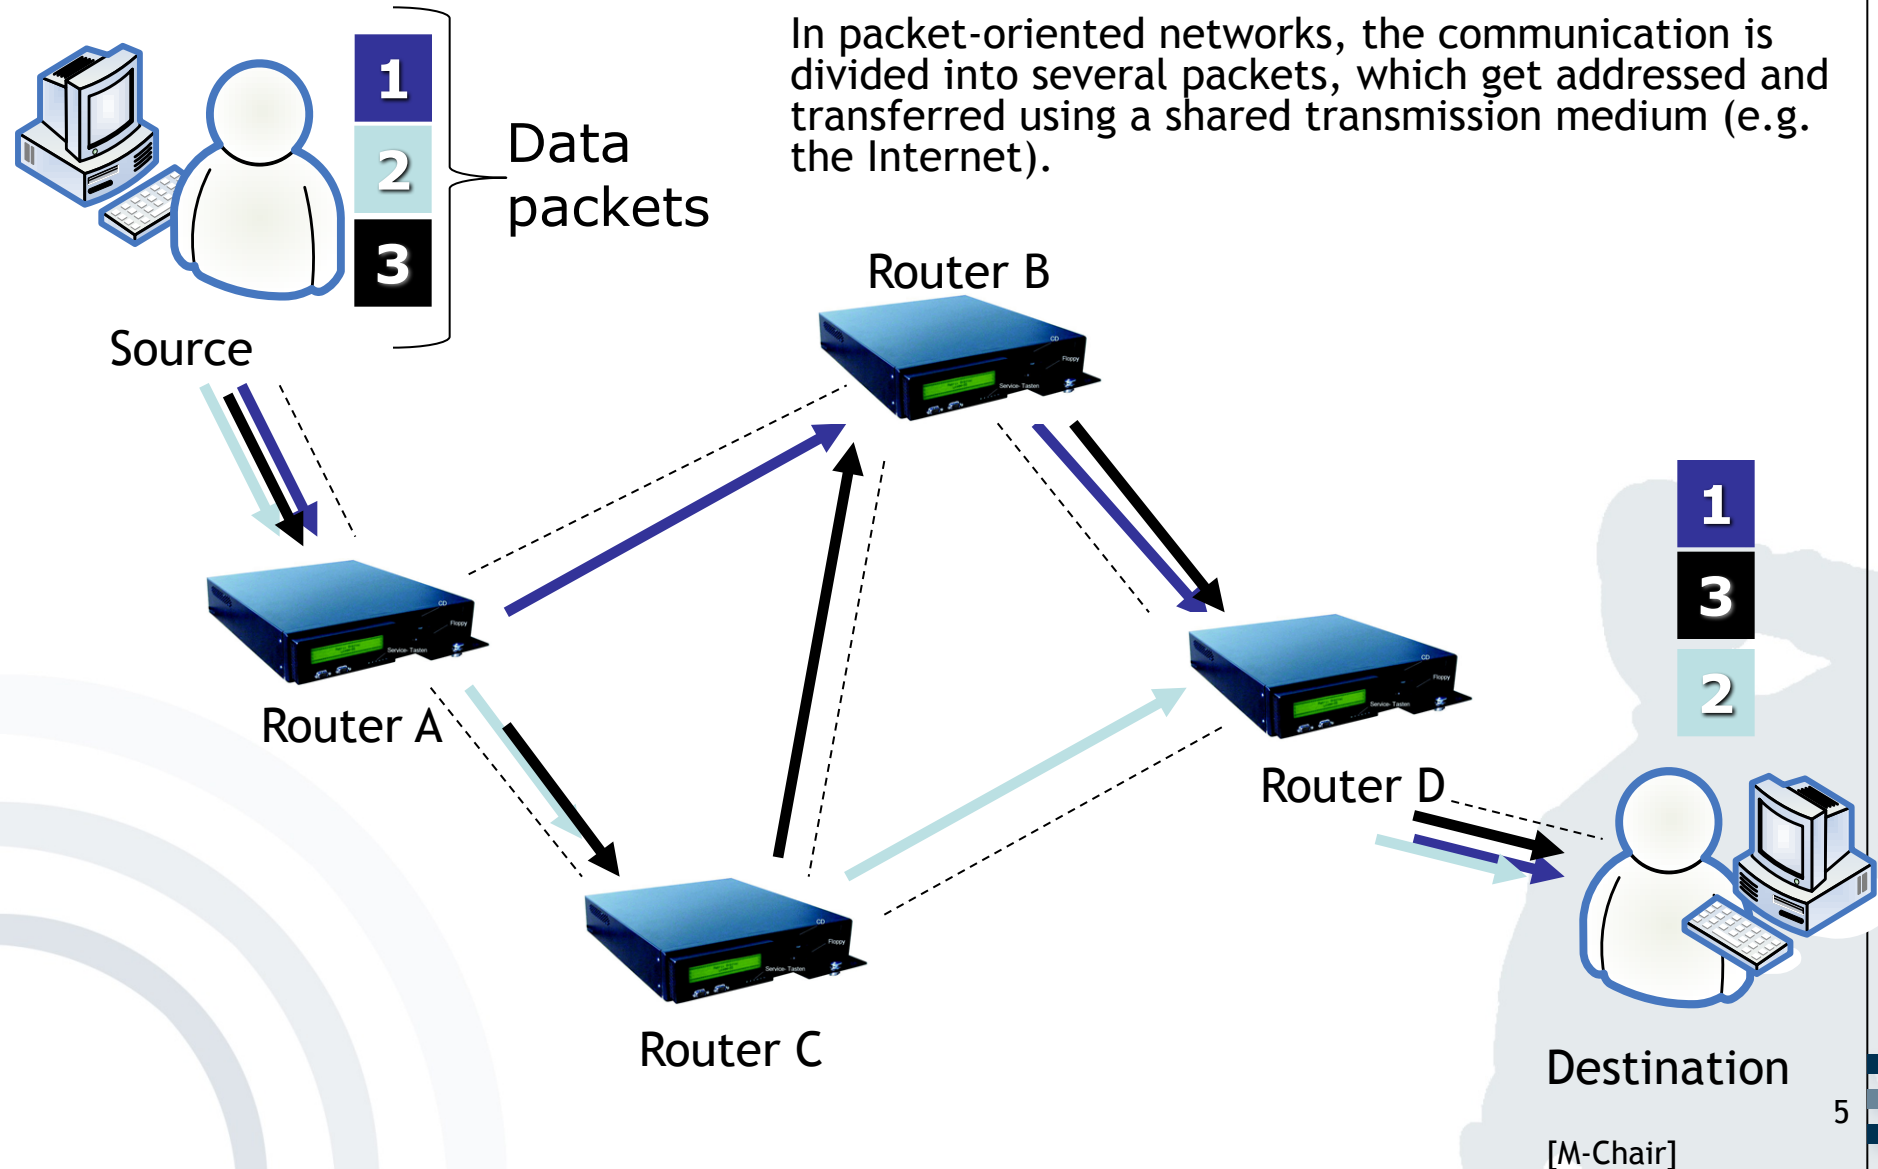

In circuit-switched networks, the communication line is used exclusively for the communicating parties (similar to the phone system, CSD and HSCSD).

[M-Chair]

Mobile Data Services Packet-Oriented Networks

In packet-oriented networks, the communication is divided into several packets, which get addressed and transferred using a shared transmission medium (e.g. the Internet).

Cell Based Communication (CBC)

What is a Cellular Network?

- Cellular networks are radio networks consisting of several transmitters.
- Each transmitter or base station, covers a certain area ➔ **a cell**.
- Cell radii can vary from tens of meters to several kilometres.
- The shape of a cell is influenced by the environment (buildings, etc) and usually neither hexagonal nor a perfect circle, even though this is the usual way of drawing them.

[M-Lehrstuhl]

- Cellular networks offer a number of advantages compared to centralised radio systems:
 - **Higher capacity:** Cells offer the possibility to “reuse” the transmission frequencies assigned to mobile devices (e.g. by multiplexing). In order to do so, the networks need a thorough planning of the position of base stations and their frequencies.
 - ➔ More users can use the infrastructure
 - **Reduced transmission power:** Reduced power usage for the mobile device, due to the fact that only a limited amount of transmission power is needed in a small cell, compared to a far away base station.
 - ➔ Reduced power consumption for mobile devices

- Cellular networks offer a number of advantages compared to centralised radio systems:
 - ***Robustness:*** Cellular systems are decentralised with regard to their base stations. In the case that one antenna fails, only a small area gets affected.
 - ➡ Failure of one base station does not affect the complete infrastructure
 - ***Better coverage:*** Cells can be adapted to geographic conditions (mountains, buildings, etc.).
 - ➡ Better availability of the infrastructure

- However, there are also some drawbacks of cell based communication infrastructures:
 - ***Required infrastructure:*** A complex and costly infrastructure is required, in order to link all base stations. This includes switches, antennas, location registers, etc.
 - ***Handover needed:*** When changing from one cell to another, a handover mechanism is needed that allows a change of cells in real-time. These mechanisms are complex.
 - ***Frequency planning:*** The distribution of the frequencies being used for the base stations needs to be planned carefully, in order to minimise interferences, etc.

- Fundamental mechanism in communication system
- Describes how several users can share a medium (e.g. mobile network) with minimum or no interference.
- **Goal:** Most efficient usage of a medium
- **Abstract example:** Traffic (users) using a highway with several lanes (medium) without accidents (interference)

Frequency range of instruments of entertainment and communication electronics

- **1st Generation (1G) - Analogue networks**
- **2nd Generation (2G) - GSM networks**
Global System for Mobile Communications
- **3rd Generation (3G/3.5G) - UMTS/HSPA/HSPA+**
Universal Mobile Telecommunications System
High Speed Packet Access / Evolved HSPA = HSPA+
- **3.9G or 4G - LTE**
Long Term Evolution
- **4th Generation (4G) - LTE Advanced**
- **5th Generation (5G) - Mobile broadband**

Evolution of mobile telecommunication infrastructures

2G – GSM

3.9G/4G – LTE

1G

3G – UMTS

4G – LTE Advanced

5G

- **1st mobile radio network in Germany: “A-Netz”**
 - Started in 1958 - decommissioned in 1977
 - Analogue network
 - Manual switching of calls
 - For a call to a mobile callee the caller or operator (switchboard clerk) needed to know the location area of the callee (range from 30 to 50 km radius).
 - Frequency range 150 MHz
 - Price of terminal: 8.000 - 15.000 DM
- **2nd mobile radio network in Germany: “B-Netz”**
 - Started in 1972 – decommissioned 1994-12-31
 - Analogue network
 - Automatic dial switching by area code
 - Caller needed to know the area and the area code of the mobile callee.
 - Terminal prices comparable to those of the “A-Netz”

- ***3rd mobile radio network in Germany: “C-Netz”***
 - Started in 1985 – decommissioned 2000-12-31
 - Analogue network
 - First ***cell based*** mobile radio system in Germany
 - The change of cells happens automatically by distance measuring to the nearest base station.
 - The net can automatically detect the place of the call partner by use of a Home Location Register (HLR)
 - Uniform (location independent) area code “0161” for all participants
 - Telephone number is not allocated to the terminal but to a magnet stripe card and later a chip card (predecessor of the GSM SIM)
 - Customer peak 1993: 850.000 participants

- In 1991, the first GSM (2G) network (“D-Netze”) started in a test run in Germany.
- By introducing the worldwide GSM-standards and roaming agreements among mobile operators cross-border mobile communication became possible.
- In 2003 the first **UMTS** (3G) networks became available.

- The radio frequencies for mobile broadband connection were auctioned in Germany (5.08 bn €) in May/June 2015.
- In 2012, the European Commission committed 50 m € for research to deliver **5G in 2020**.
- First **Long Term Evolution Networks (3.9G/4G)** became **commercially available** in Stockholm and Oslo in 2009.
- On April and May 2010, the **digital dividend** frequency spectrum auctioned in Germany (4.4 bn €) for
 - use in Long Term Evolution Networks (3.9G/4G)
 - improving broadband coverage

Unique users of GSM and related networks

Recent development

- Transmission Paradigms
- Cell Based Communication (CBC)
 - Introduction
 - Basic Technology (Cells, Multiplexing)
- Mobile Telecommunication Infrastructures
 - Introduction
 - GSM (Technology, Authentication, Location Management) (2G)
 - UMTS (3G)
 - Long Term Evolution (3.9G, 4G)
 - 5th Generation (5G): mobile broadband
- Roaming

- Abbreviation for **G**lobal **S**ystem for **M**obile Communications (GSM)

- Originally 1982 driven by “*Groupe Spéciale Mobile*” in order to create a cross national standard contrary to national analogue standards
- European standard by *ETSI* (European Telecommunications Standardisation Institute). ETSI is a partner in the 3rd Generation Partnership Project (3GPP).

- Worldwide adoption of the standard in more than *212 countries and territories* (most successful mobile radio system up to now)
- Thus, worldwide roaming among different mobile network operators became possible.

■ GSM-Services

■ Carrier services

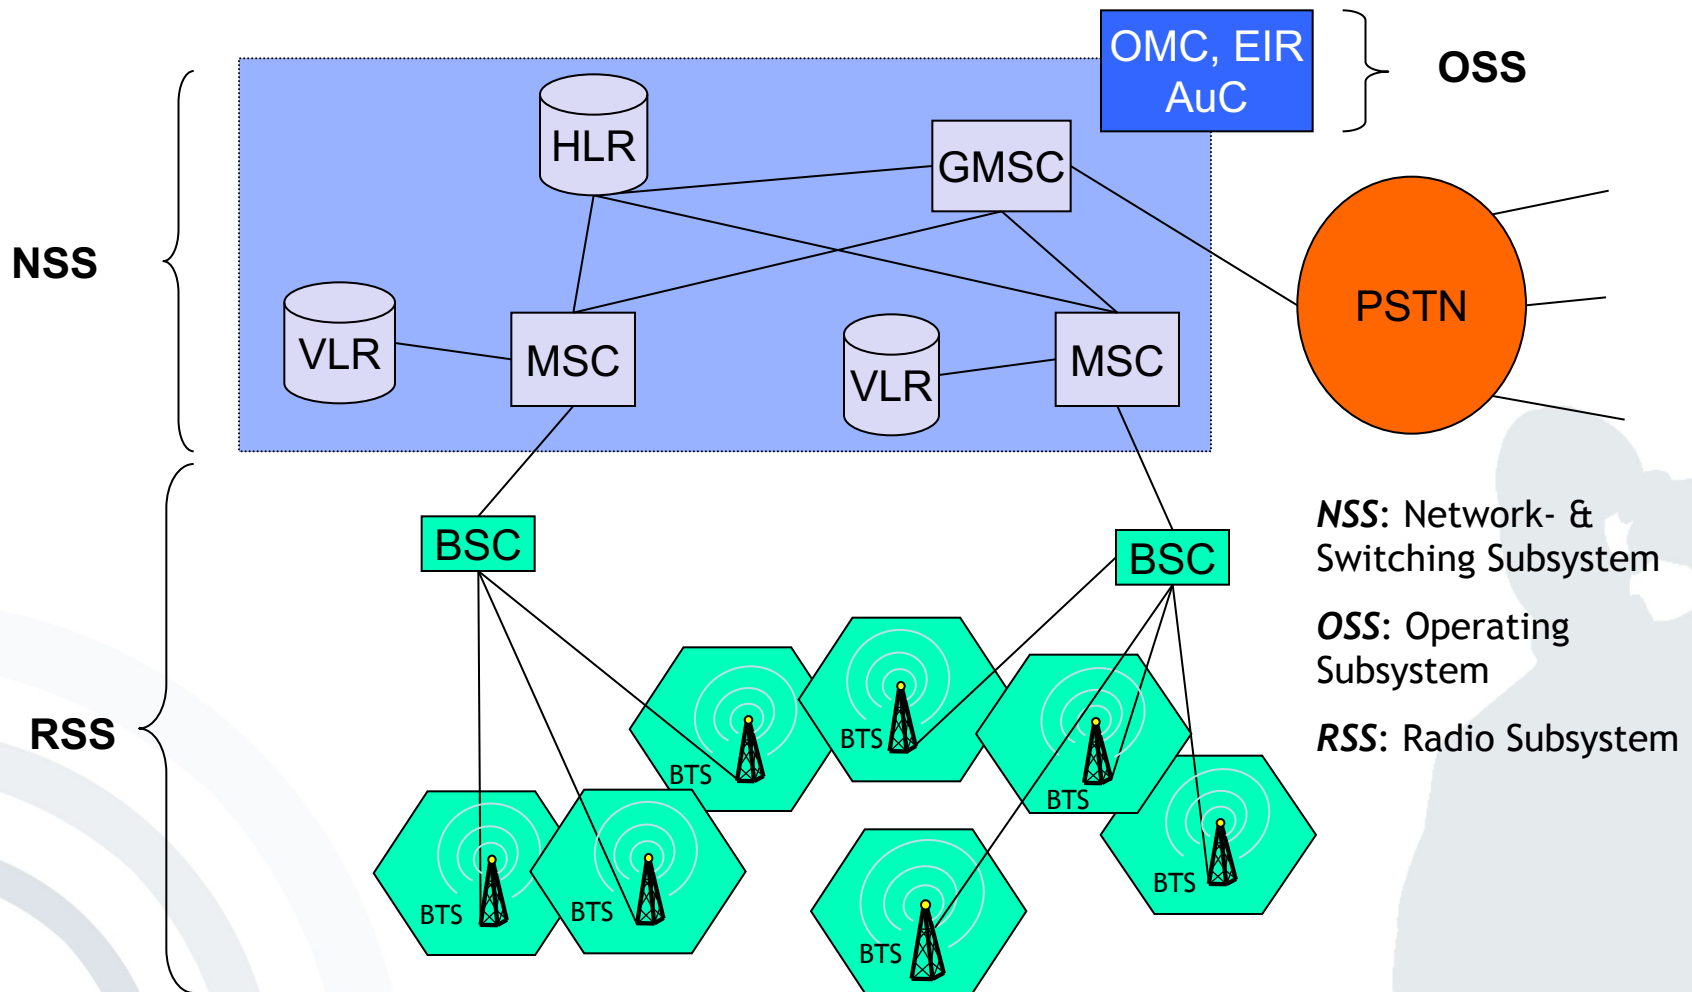

- Services to transfer signals over the GSM network
→ The focus of GSM standardization was on voice services

■ Telecommunications services

- Telecommunication services (mainly voice) support the mobile communications among users
→ Telecommunication services play a central role in the GSM standard

■ Supplementary services

- GSM provides a number of supplementary services (specific to network operators), such as caller ID, call redirect, closed user groups (e.g. company-internal network or GSM-R), Teleconference (up to 7 participants).

NSS: Network- & Switching Subsystem

OSS: Operating Subsystem

RSS: Radio Subsystem

- **Radio Subsystem (RSS)**

- System consisting of radio
- Specific components

- **Components:**

- **Mobile Station (MS):** System of mobile terminal & SIM
- **Base Transceiver Station (BTS):** Radio facility for signal transfer. A BTS serves one GSM cell (~100m to ~30km radius).
- **Base Station Controller (BSC):** Administrates affiliated BTS and supervises e.g. frequency allocation and connection handover between cells.

- **Network & Switching Subsystem (NSS)**

- Connects radio network with conventional networks
- Locates subscribers and monitors change of location

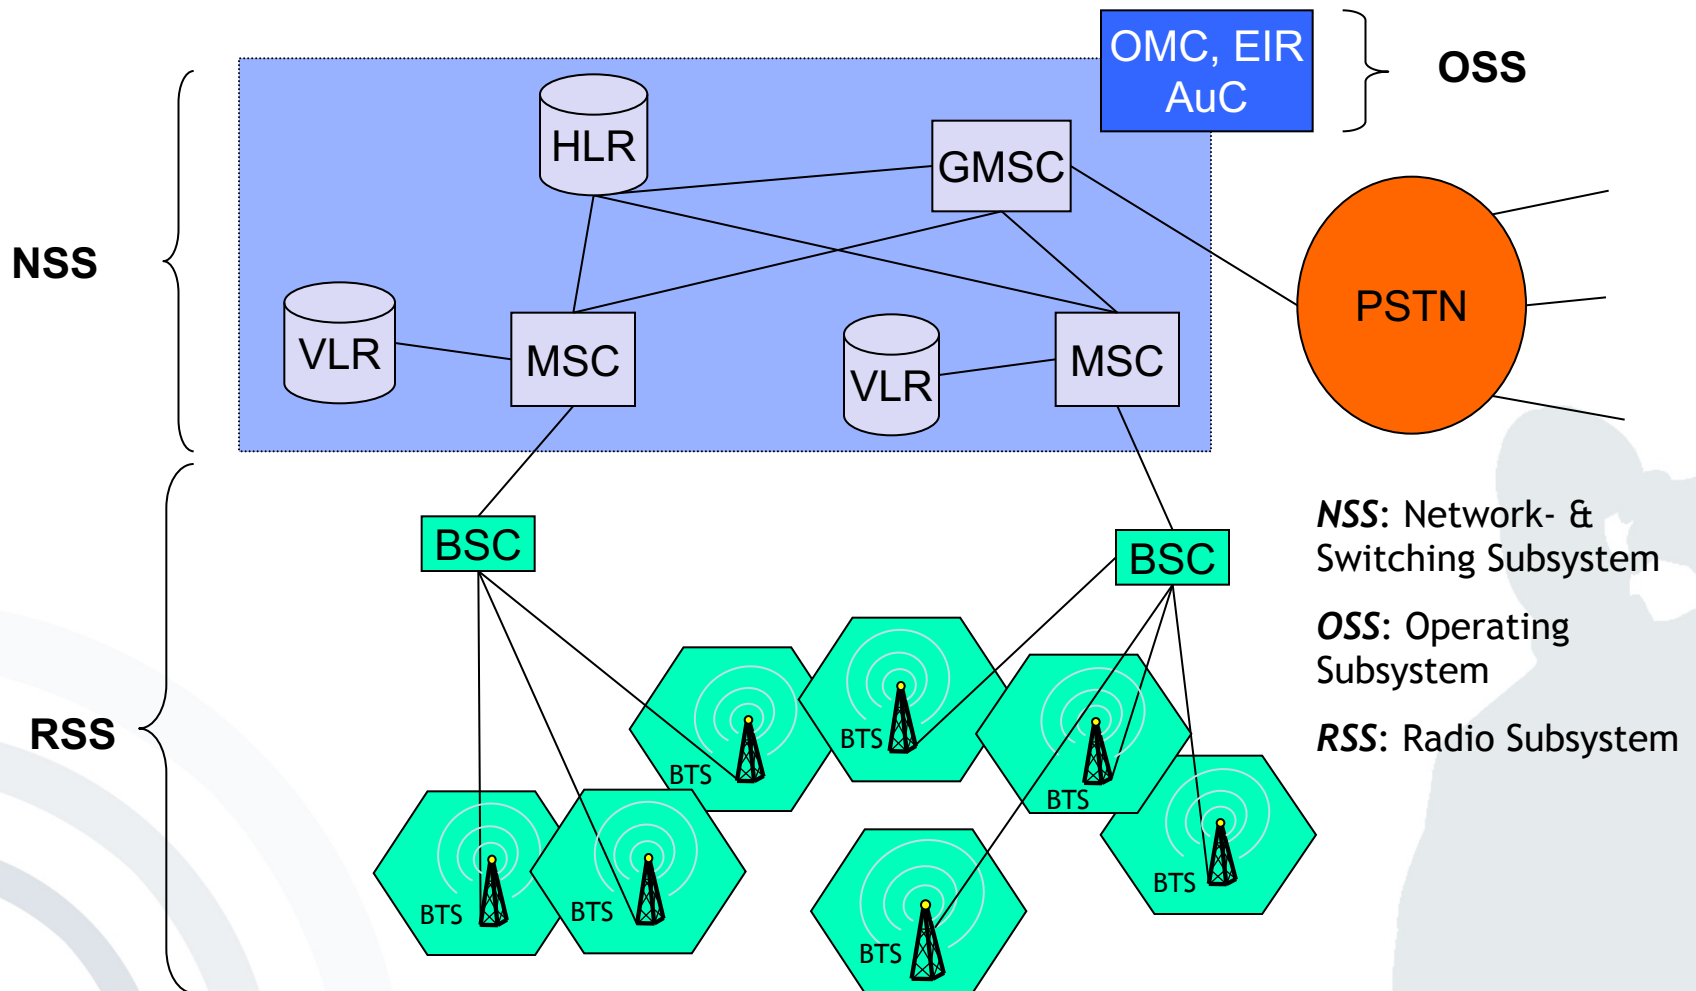

- **Components:**

- **Mobile Switching Centre (MSC):** Switching centre for initiation, termination and handover of connections
- **Home Location Register (HLR):** Central data base with subscribers' data (telephone numbers, keys, locations)
- **Visitor Location Register (VLR):** Data base assigned to every MSC with data of active subscribers in the MSC's range (HLR fraction copy).

- Transferral of calls or data sessions from one transmitting station (in GSM: Base Transceiver Station, BTS) to another.
- Term **handover** common in British English
 - In international and Europe based organisations, e.g. ITU-T, IETF, ETSI and 3GPP
- Equivalent term **handoff** in American English
 - In IEEE and ANSI publications

- **Operation Subsystem (OSS)**

- Supervises operation and maintenance of the whole GSM network

OSS

OMC, EIR
AuC

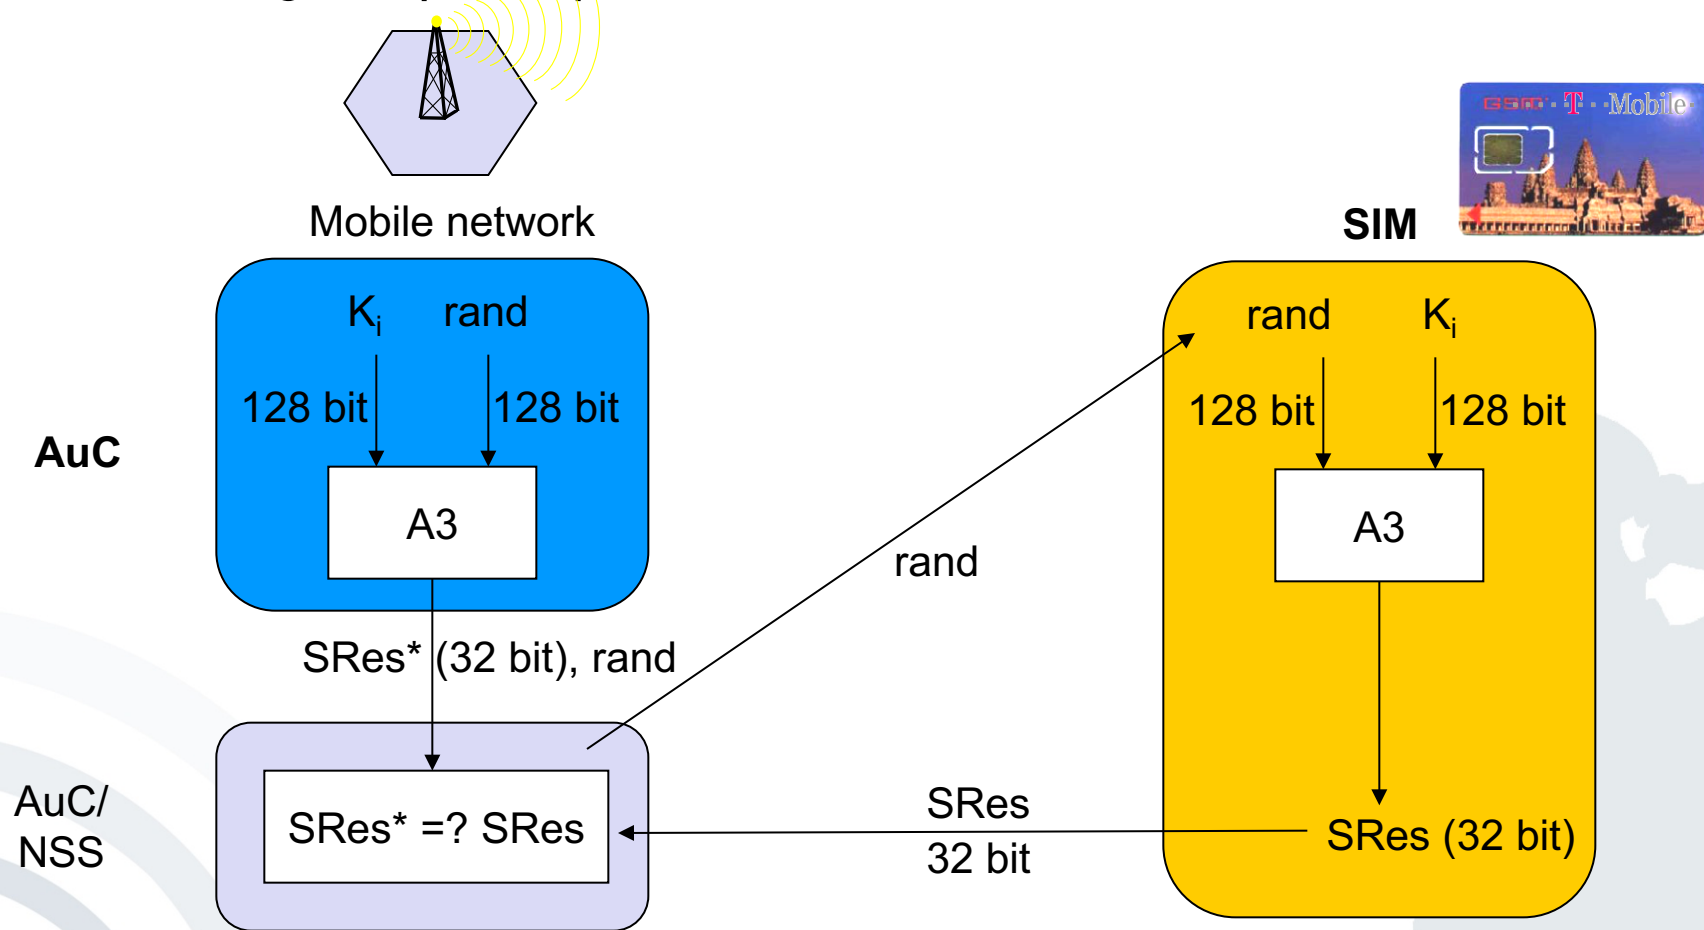

- **Components:**

- **Operation and Maintenance Centre (OMC):** Supervises each network component and creates status reports
- **Authentication Centre (AuC):** protects identity of participants & data transmission, administrates keys
- **Equipment Identity Register (EIR):** data base with identification list for devices, e.g. stolen terminals (whitelist, greylist, blacklist)

The GSM system offers different “security services”:

- **Access control and authentication:**
 - Authentication of the subscriber to the SIM by input of a PIN and to the GSM network by Challenge-Response-Procedure
- **Confidentiality:**
 - Data & voice transferred between mobile station and BTS are encrypted.
- **(Partial) Anonymity:**
 - No transfer of data which can identify the subscriber via radio, instead temporary identification
 - (Temporary Mobile Subscriber ID, TMSI)

- Challenge response protocol

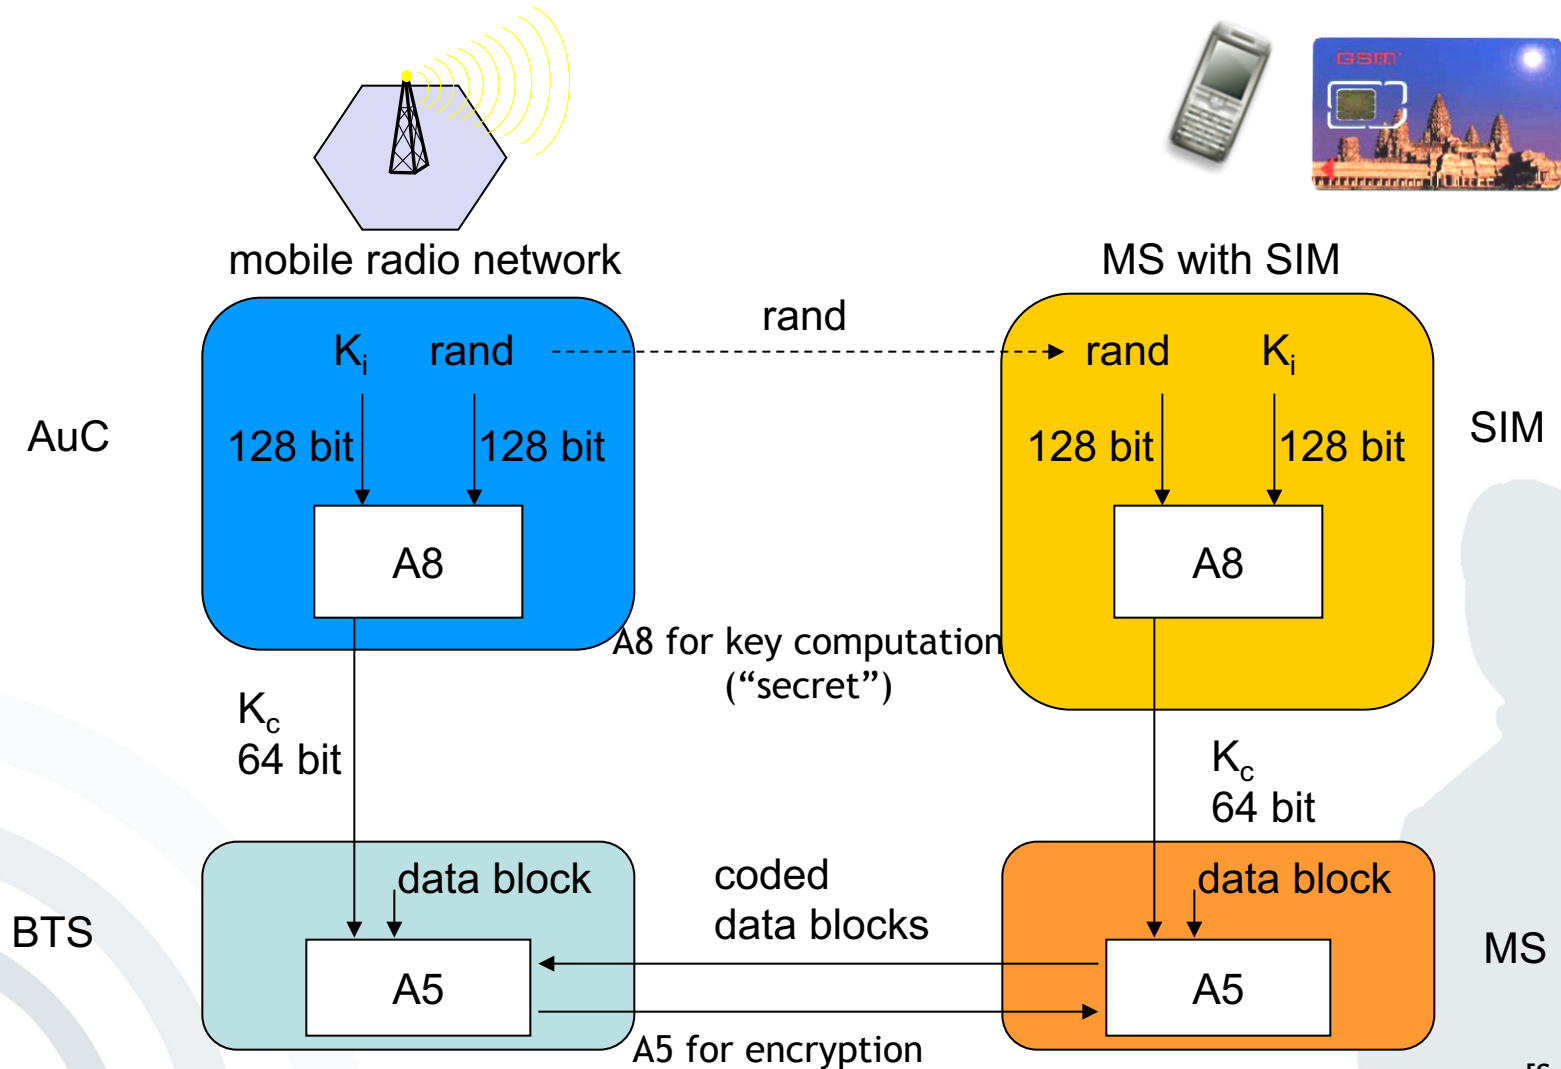

K_i : individual subscriber authentication key

A3: („secret“) authentication algorithm

SRes: signed response

- Challenge-Response-Procedure (Subscriber Authentication)
Authentication is based on the individual key K_i , the subscriber identification IMSI and a secret algorithm A3.
- K_i and A3 are stored on the SIM and deposited in the AuC.
 1. AuC creates random number *rand*.
 2. AuC encrypts *rand* and K_i via A3 (-> SRes*).
 3. AuC transfers *rand* and SRes* to VLR.
 4. VLR transfers exclusively *rand* to SIM.
 5. SIM computes with “own” K_i and A3 Signed Response SRes.
 6. The SRES computed by the SIM is transmitted to the VLR and is compared with SRES*.
 7. If SRES* and SRES are equal the subscriber is authenticated successfully.

- **GSM provides encryption of voice and data transferred via the air interface:**
 1. AuC creates random number rand.
 2. AuC generates the key K_c for the encryption of the transferred data via rand, K_i and A8.
 3. VLR transfers only rand to SIM.
 4. SIM computes the key K_c using A8, the rand received and the local K_i
 5. Mobile station and mobile radio network use generated K_c and algorithm A5 for encryption and decryption of sent and received data.

- Partial Anonymity:
 - In order to guarantee the anonymity of the users temporary user identification (TMSI) is used.
 - Temporary user identification is updated automatically from time to time or on demand.
 - Data which identify users are not transferred.
 - **Example:** Anonymous charging is (technically) possible via prepaid card.

- Solely authentication of the terminal/subscriber toward the GSM network. The network does not authenticate itself.
 - Assumption that the network is trustworthy per se
 - Security model was developed at a time with a provider monopoly
- Subscriber localization is almost exclusively controlled by the network.
 - Centralized movement tracking is possible
 - In order to avoid localization the subscriber must switch off the terminal.

- Security model bases partly on secret encryption algorithms.
 - A3 and A8 were published without authorization.
 - Some operators use non-standardized algorithms.
- No encryption from terminal to terminal but solely over the air interface
 - Encryption deactivation by the network possible, without notification of the users
- Encryption comparatively “weak” because of key length (64 bit)
 - Sometimes the real key length is shorter.

 - UMTS (3G)
 - Long Term Evolution (3.9G, 4G)
 - 5th Generation (5G): mobile broadband
- Roaming

- Universal Mobile Telecommunications System (UMTS):
 - **Status of 2G-Networks:** Different standards in some different continents avoid worldwide roaming
 - **Demand for 3G-Networks:** Globally uniform standard

➔ Voting of regional & national regulation offices (e.g. ETSI, ARIB, ANSI) via the International Telecommunication Union (ITU)

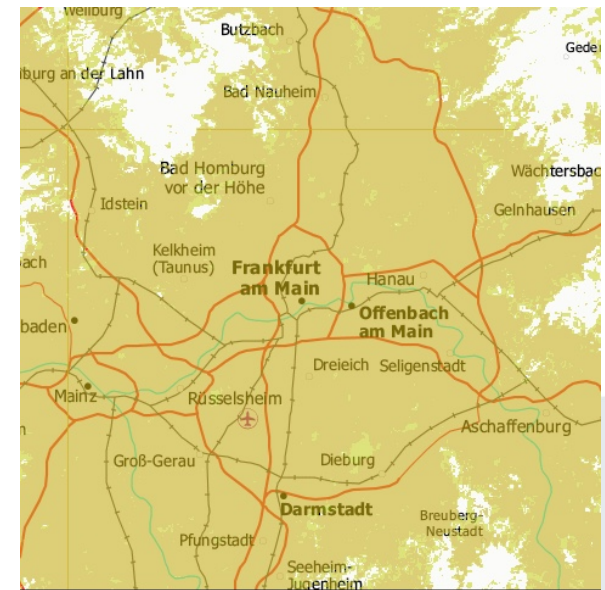

Telekom

Vodafone

Telefónica

- **Common approach:**
Worldwide reservation of frequencies in the 2GHz range
- **Problem of competing targets:**
 - Existing national networks and installed network technique shall preferably be transferred into the new standard.
 - ➡ The specification of 3G-Networks, introduced by the ITU, leaves room for national, partly incompatible implementations.

UMTS Core network

- is not shown here in detail
- UMTS Core network corresponds to Network- & Switching Subsystem (NSS) in GSM

- 3G UMTS/HSPA/HSPA+ bandwidths
 - UMTS: 384 kbit/s downlink/uplink
 - High Speed Packet Access (HSPA) provides higher data speeds for downlink and uplink, e.g.
 - 7.2 or 14.0 Mbit/s downlink speed (HSDPA)
 - 1.4 or 5.7 Mbit/s uplink speed (HSUPA).
 - Evolved HSPA (HSPA+) using either *Multiple Input Multiple Output (MIMO)* or *Dual-Cell* technology provides
 - downlink speeds of e.g. 21,1 or 42,2 Mbit/s and
 - a maximum uplink speed of 11.5 Mbit/s.
 - But: Available bandwidth per user decreases if terminal is moving or if there are many participants in one radio cell.
- ➡ Bandwidths enable multimedia services

- UMTS complements the security mechanisms known by GSM:
 - Enhanced participant authentication (EMSI)
 - Network authentication
 - Integrity protection of data traffic
 - Transferred security keys are also encrypted in the fixed network (e.g. HLR-VLR)
 - Increased key length
 - End-to-End encryption is possible.

- The UMTS standard includes the following features:
 - Quality of Service (QoS) for data services
 - Multilateral Security (with regard to authentication)
 - Virtual Home Environment (VHE)
 - High Speed Downlink Packet Access (HSDPA)
 - ...
- However, not **all** of these features that have been standardised are actually implemented in existing networks, as they are optional and can be added on demand.

- Transmission Paradigms

 - UMTS (3G)
 - Long Term Evolution (3.9G, 4G)
 - 5th Generation (5G): mobile broadband
- Roaming

- **Long Term Evolution (3.9G, “4G”)** standard allows for 300 Mbit/s downlink and 75 Mbit/s uplink speeds
 - First commercial LTE network launched in Scandinavia in December 2009
 - LTE was originally not named a “4G network” due to stricter naming requirements *)
 - The technology can be named either 3.9G or 4G network today.
- **LTE Advanced (4G)** makes use of the frequency spectrum more efficiently, resulting in higher data rates (towards 1 Gbit/s) and lower latency. It remains backward compatible with LTE, uses same frequency bands.

<http://www.3gpp.org/LTE>

<http://www.3gpp.org/LTE-Advanced>

*) A 4G service was originally defined as meeting the *IMT-Advanced* requirements issued by the ITU-R. For more information see [Parkvall2008].

- LTE networks are **IP-based systems** (all-IP networks)
 - Voice calls in GSM and 3G (UMTS) are **circuit-switched**.
 - Only **packet-switched** communication is supported in LTE networks - no circuit-switched connections/calls/telephony!
- Four different approaches to provide telephony services in Long Term Evolution networks:
 - **CSFB** (Circuit Switched Fallback)
 - **VoLGA** (Voice over LTE via GAN - Generic Access Network)
 - **VoLTE (Voice Over LTE)** based on the IP Multimedia Subsystem (IMS) network.
 - **SVLTE** (Simultaneous Voice and LTE, handset-based approach)

Two views of 5G:

- **View 1** - The hyper-connected vision
- **View 2** - Next-generation radio access technology

5G technology promises

- 1 millisecond end-to-end round trip delay (latency)
- 1-10 Gbps connections to end points in the field (i.e. not theoretical maximum)
- 1000 x bandwidth per unit area
- 10-100 x number of connected devices
- 99.999 % availability
- 100 % geographical coverage
- 90 % reduction in network energy usage
- Up to ten year battery life for low power, machine-type devices

[GSMA5G]

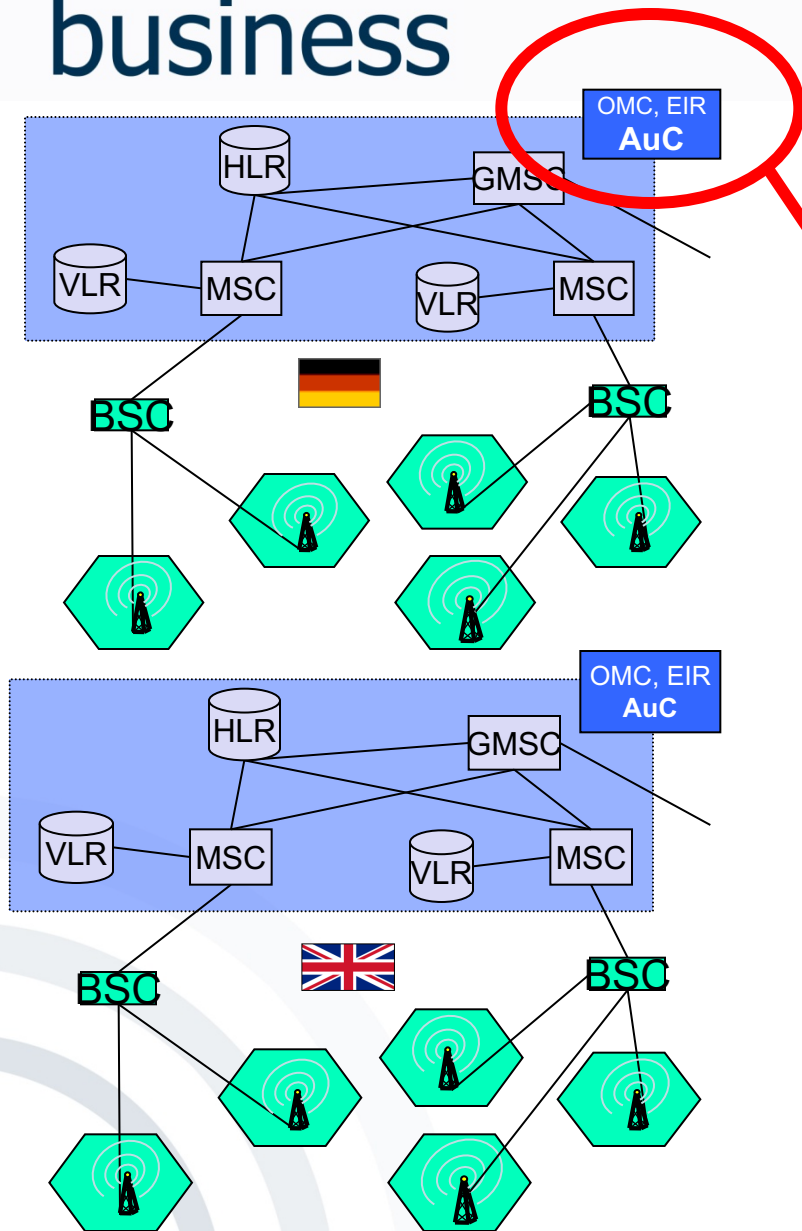

- Autonomous driving/Connected cars
- Wireless cloud-based office/Multi-person videoconferencing
- Machine-to-machine connectivity (M2M)
 - vehicle telemetric systems (a field which overlaps with Connected cars above)
 - ‘connected home’ systems (e.g. smart meters, smart thermostats, smoke detectors)
 - consumer electronics and healthcare monitoring.
- Virtual Reality/Augmented Reality/Immersive or Tactile Internet

- Transmission Paradigms
- Cell Based Communication (CBC)
 - Introduction
 - Basic Technology (Cells, Multiplexing)
- Mobile Telecommunication Infrastructures
 - Introduction
 - GSM (Technology, Authentication, Location Management) (2G)
 - UMTS (3G)
 - Long Term Evolution (3.9G, 4G)
 - 5th Generation (5G): mobile broadband
- Roaming

- Roaming denotes a change of network access, e.g.:
 - Change of the GSM network operator
 - Change between different network systems (UMTS, GSM, WLAN, CDMA, PDC)
 - Cell change within the GSM system (Handover)
- Roaming usually means extensive changes, e.g. of the network technique or the network operator, and with a new authentication:
 - **Example:** The mobile device automatically logs into an available WLAN when a hotspot is entered (e.g. airport, conferences).

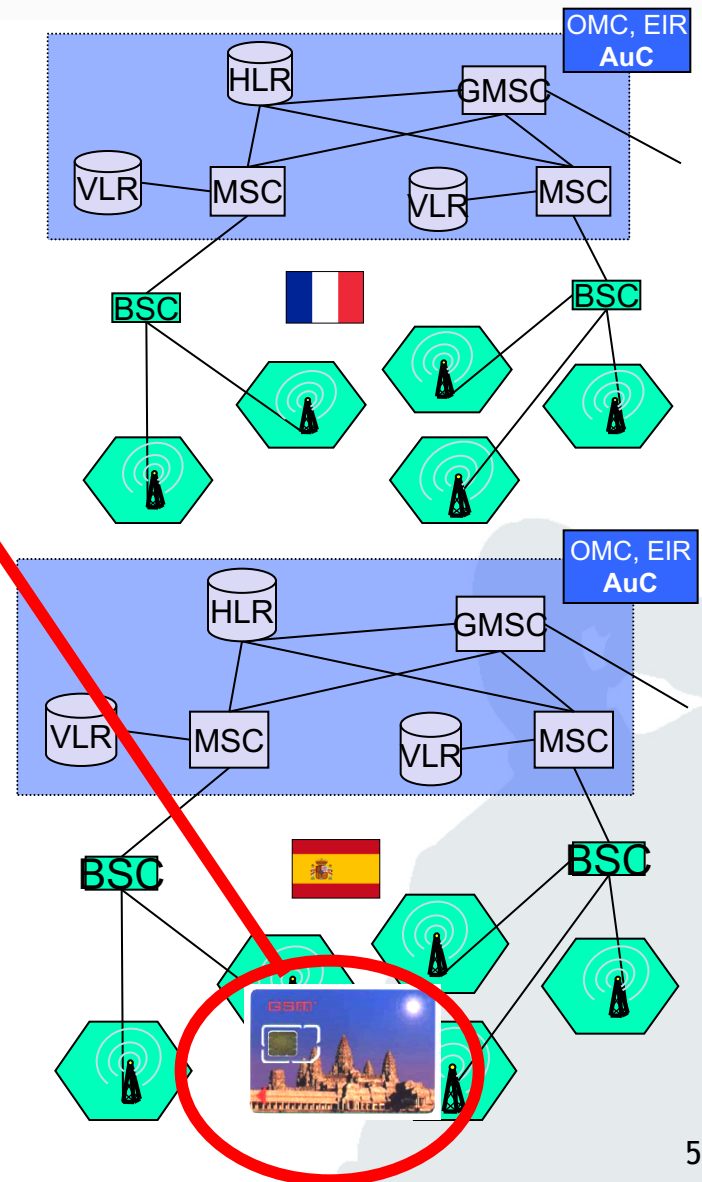

- If a user of a mobile device moves from one cell to another cell, the connection handover should be as smooth as possible.
- GSM manages the handover between radio cells in the range of 100 ms; this implies a short connection interruption.
- The reason for the interruption is, among others, an update of the VLR.

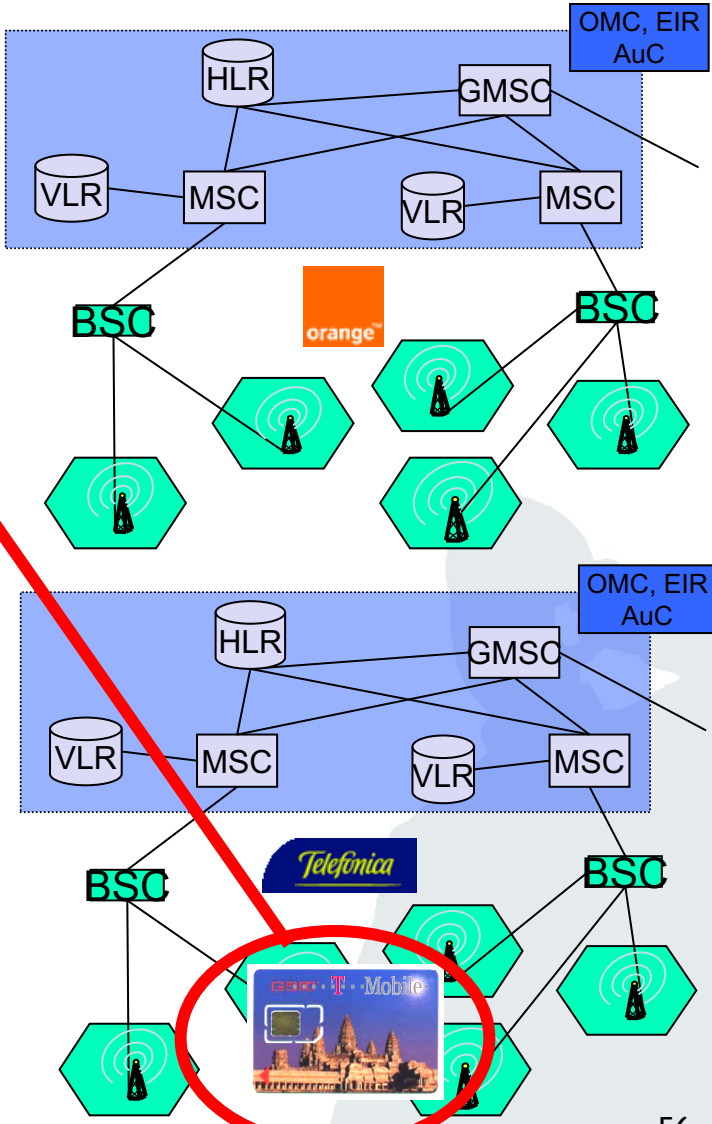

Roaming

SIM Based Roaming
